1 NAME

DBI.pm - provides DBI-based implementation of the OpenSLX MetaDB API.

2 SYNOPSIS

This class is the base for all DBI-related metaDB variants. It provides a default implementation for every method, such that each DB-specific implementation needs to override only the methods that require a different implementation than the one provided here.

3 NOTES

In case you ask yourself why none of the SQL-statements in this file make use of SQL bind params (?), the answer is that at least one DBD-driver didn't like them at all. As the performance gains from bound params are not really necessary here, we simply do not use them.
